

PAID SERVERS & DEPLOYMENT CONSTRAINTS

REQUIRED

The **NEXORA** screening platform was architected, trained, and validated using a hybrid local development stack utilizing Google Colab runtime GPU/CPU environments and temporary secure ngrok tunneling to handle high-compute Machine Learning (ML) inferencing for both the PHQ-9 depression screening and Lifestyle Risk assessment models.

NEXORA is designed as a specialized B2B enterprise module intended for direct integration into existing hospital management infrastructure and internal patient portals. It is not **conceived or built as a standalone B2C public web application**.

1. **Enterprise Deployment Model:** The system is engineered to run behind internal hospital firewalls to preserve data sovereignty and patient privacy. Deploying it publicly defeats its core design as a B2B institutional solution.
2. **ML Infrastructure Costs:** Real-time ML inference for the PHQ-9 and Lifestyle Risk assessment models requires persistent GPU/CPU instances, automated database clusters, and dedicated dynamic domain hosting incurring ongoing paid server costs beyond the scope of academic prototyping.
